Chapter 1

Introduction

This document is a technical reference to the in-EVM Mina state verification project.

1.1 Overview

The project's purpose is to provide Ethereum users with reliable Mina Protocol's state proof. The project UX consists of several steps:

1. Retrieve Mina Protocol's state proof.
2. Preprocess it by generating an auxiliary proof.
3. Submit the preprocessed proof to EVM-enabled cluster.
4. Verify the proof with EVM.

Such a UX defines projects parts:

1. Mina Protocol's state retriever (O1Labs' or Chainsafe's protocol implementation).
2. State proof generator.
3. Ethereum RPC proof submitter.
4. EVM-based proof verifier.

Each of these parts will be considered independently.

Chapter 2

State Proof Generator

This introduces a description for Mina Protocol’s state auxiliary proof generator. Crucial components which define this part design and performance are:

1. Input data format (Pickles proof data structure: [2.5.2](#))
2. Proof system used for the proof generation.
3. Circuit definition used for the proof system.

2.1 Introduction

WIP

To prove Mina blockchain’s state on the Ethereum Virtual Machine, we use Redshift SNARK[[1](#)]. RedShift is a transparent SNARK that uses PLONK[[2](#)] proof system but replaces the commitment scheme. The authors utilize FRI[[3](#)] protocol to obtain transparency for the PLONK system.

However, FRI cannot be straightforwardly used with the PLONK system. To achieve the required security level without huge overheads, the authors introduce *list polynomial commitment* scheme as a part of the protocol. For more details, we refer the reader to [[1](#)].

The original RedShift protocol utilizes the classic PLONK[[2](#)] system. To provide better performance, we generalize the original protocol for use with PLONK with custom gates [[4](#)], [[5](#)] and lookup arguments [[6](#)], [[7](#)].

2.2 Optimizations

WIP

2.2.1 Batched FRI

Instead of checking each commitment individually, it is possible to aggregate them for FRI. For polynomials f_0, \dots, f_k :

1. Get θ from transcript
2. $f = f_0 \cdot \theta^{k-1} + \dots + f_k$
3. Run FRI over f , using oracles to f_0, \dots, f_k

Thus, we can run only one FRI instance for all committed polynomials. See [[1](#)] for details.

2.2.2 Hash By Column

Instead of committing each of the polynomials, it is possible to use the same Merkle tree for several polynomials. This leads to the decrease of the number of Merkle tree paths which are required to be provided by the prover.

See [[8](#)], [[1](#)] for details.

2.2.3 Hash By Subset

Each $i + 1$ FRI round supposes the prover to send all elements from a coset $H \in D^{(i)}$. Each Merkle leaf is able to contain the whole coset instead of separate values.

See [8] for details. Similar approach is described in [1]. However, the authors of [1] use more values per leaf, that leads to better performance.

2.3.1 Prover View

1. Choose masking polynomials:

$$h_i(X) \leftarrow \mathbb{F}_{<k}[X] \text{ for } 0 \leq i < N_{\text{wires}}$$

Remark: For details on choice of k , we refer the reader to [1].

2. Define new witness polynomials:

$$f_i(X) = \mathbf{f}_i(X) + h_i(X)Z(X) \text{ for } 0 \leq i < N_{\text{wires}}$$

3. Add commitments to f_i to transcript
4. Get $\beta, \gamma \in \mathbb{F}$ from $\text{hash}(\text{transcript})$
5. For $0 \leq i < N_{\text{perm}}$

$$\begin{aligned} p_i &= f_i + \beta \cdot S_{id_i} + \gamma \\ q_i &= f_i + \beta \cdot S_{\sigma_i} + \gamma \end{aligned}$$

6. Define:

$$\begin{aligned} p'(X) &= \prod_{0 \leq i < N_{\text{perm}}} p_i(X) \in \mathbb{F}_{<N_{\text{perm}} \cdot n}[X] \\ q'(X) &= \prod_{0 \leq i < N_{\text{perm}}} q_i(X) \in \mathbb{F}_{<N_{\text{perm}} \cdot n}[X] \end{aligned}$$

7. Compute $P(X), Q(X) \in \mathbb{F}_{<n+1}[X]$, such that:

$$\begin{aligned} P(\omega) &= Q(\omega) = 1 \\ P(\omega^i) &= \prod_{1 \leq j < i} p'(\omega^j) \text{ for } i \in 2, \dots, n+1 \\ Q(\omega^i) &= \prod_{1 \leq j < i} q'(\omega^j) \text{ for } i \in 2, \dots, n+1 \end{aligned}$$

10. Get τ from $\text{hash}(\text{transcript})$

11. Define polynomials (F_0, \dots, F_4 - copy-satisfiability, \mathbf{gate}_0 is PI -constraining gate)):

$$\begin{aligned} F_0(X) &= L_1(X)(P(X) - 1) \\ F_1(X) &= L_1(X)(Q(X) - 1) \\ F_2(X) &= P(X)p'(X) - P(X\omega) \\ F_3(X) &= Q(X)q'(X) - Q(X\omega) \\ F_4(X) &= L_n(X)(P(X\omega) - Q(X\omega)) \\ F_5(X) &= \sum_{0 \leq i < N_{\text{sel}}} (\tau^i \cdot \mathbf{q}_i(X) \cdot \mathbf{gate}_i(X)) + PI(X) \end{aligned}$$

12. Compute:

$$\begin{aligned} F(X) &= \sum_{i=0}^5 \alpha_i F_i(X) \\ T(X) &= \frac{F(X)}{Z(X)} \end{aligned}$$

High level description according to RfP²

1. Computing several hash values from the data of the proof. This involves using the Poseidon hash function with 55 full rounds both over \mathbb{F}_p and \mathbb{F}_q with round constants and MDS matrix specified for \mathbb{F}_p ³ and for \mathbb{F}_q ⁴.
2. Checking arithmetic equations.
3. Performing one multi-scalar multiplication (MSM) of size $2n_2 + 4 + (2 + 25) = 63$, for which some of the bases are fixed and some are variable.
4. For each $i \in \{1, 2\}$, performing a multi-scalar multiplication over \mathbb{G}_i of size 2^{n_i} with a fixed array of bases, and with scalars that can be very efficiently computed from the proof.

Note that for MSM in Step 4:

$$\sum_{i=0}^{2^{n_k}-1} s_i \cdot G_i = H$$

$$s_i := \prod_{\substack{0 \leq j \leq n_k \\ \text{bits}(i)[j]=1}} \phi(c_j),$$

where:

- $\phi: \{0, 1\}^{128} \rightarrow \mathbb{F}$ is defined as `to_field` in the implementation⁵.
- Given an integer $i < 2^{n_k}$, $\text{bits}(i)$ is defined as the little-endian bit array of length n representing the binary expansion of i .
- $G_0, \dots, G_{2^{n_k}-1} \in \mathbb{G}_k$ is a fixed sequence of group elements⁶.
- $c_0, \dots, c_{n_k-1} \in \{0, 1\}^{128}$ is a sequence of challenges.

We use the same 15-wires PLONK circuits that are designed for Mina.⁷

Input: $G_0, \dots, G_{k-1} \in \mathbb{G}, s_0, \dots, s_{k-1} \in \mathbb{F}_r$, where \mathbb{F}_r is scalar field of \mathbb{G} .

Output: $S = \sum_{i=0}^k s_i \cdot G_i$

2.7.1 Naive Algorithm

Using endomorphism:

1. $A = \infty$
2. for j from 0 to $k - 1$:
 - 2.1 $r := s_j, T := G_j$
 - 2.2 $S = [2](\phi(T) + T)$
 - 2.3 for i from $\frac{\lambda}{2} - 1$ to 0:
 - 2.3.1 $Q = r_{2i+1} ? \phi([2r_{2i} - 1]T) : [2r_{2i} - 1]T$

$$2.3.2 \ R = S + Q$$

$$2.3.3 \ S = R + S$$

$$2.4 \ A = A + S$$

$$\text{rows} \approx k \cdot (\text{sm_rows} + 1 + 2) \approx 67k,$$

where `sm_rows` is the number of rows in the scalar multiplication circuit.

Without endomorphism:

$$1. \ A = \infty$$

$$2. \ \text{for } j \text{ from } 0 \text{ to } k - 1:$$

$$2.1 \ r := s_j, T := G_j$$

$$2.2 \ S = [2]T$$

$$2.3 \ \text{for } i \text{ from } n - 1 \text{ to } 0:$$

$$2.3.1 \ Q = k_{i+1} ? T : -T$$

$$2.3.2 \ R = S + Q$$

$$2.3.3 \ S = R + S$$

$$2.4 \ S = k_0 ? S - T : S$$

$$2.5 \ A = A + S$$

$$\text{rows} \approx k \cdot (\text{sm_rows} + 1 + 1) \approx 105k,$$

where `sm_rows` is the number of rows in the scalar multiplication circuit.

2.7.2 Simultaneous Doubling

Remark: Simultaneous doubling incurs a negligible completeness error for independently chosen random terms of the sum.

Using endomorphism:

$$1. \ A = \sum_{j=0}^k [2](\phi(G_j) + G_j)$$

$$2. \ \text{for } i \text{ from } \frac{\lambda}{2} - 1 \text{ to } 0:$$

$$2.1 \ \text{for } j \text{ from } 0 \text{ to } k - 1:$$

$$2.1.1 \ r := s_j, T := G_j$$

$$2.1.2 \ Q = r_{2i+1} ? \phi([2r_{2i} - 1]T) : [2r_{2i} - 1]T$$

$$2.1.3 \ A = A + Q$$

$$2.2 \ \text{if } i \neq 0:$$

$$2.2.1 \ A = 2 \cdot A$$

$$\text{rows} \approx \frac{\lambda}{2} \cdot (k \cdot \text{add_rows} + \text{dbl_rows}) + 2k \approx 64 \cdot (k + 1) \approx 66k + 64,$$

where

- `add_rows` is the number of rows in the addition circuit.
- `dbl_rows` is the number of rows in the doubling circuit.

Without endomorphism:

1. $A = \sum_{j=0}^k [2]G_j$
2. for i from $n - 1$ to 0:
 - 2.1 for j from 0 to $k - 1$:
 - 2.1.1 $r := s_j, T := G_j$

 - 2.1.3 $A = A + Q$
 - 2.2 if $i \neq 0$:
 - 2.2.1 $A = 2 \cdot A$
3. $A = A + \sum_{j=0}^k [1 - s_{j,0}]G_j$

$$\text{rows} \approx \frac{2}{5}n \cdot (k \cdot \text{add_rows} + \text{dbl_rows}) + k \approx 103 \cdot (k + 1) + 2k \approx 104k + 103,$$

where

- **add_rows** is the number of rows in the addition circuit.
- **dbl_rows** is the number of rows in the doubling circuit.

2.8 Poseidon Circuit

WIP

Mina uses Poseidon hash with width = 3. Therefore, each permutation state is represented by 3 elements and each row contains 5 states.

Denote i -th permutation state by $T_i = (T_{i,0}, T_{i,1}, T_{i,2})$.

Row	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14

\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots

State change constraints:

$$\text{STATE}(i + 1) = \text{STATE}(i)^\alpha \cdot \text{MDS} + \text{RC}$$

Denote the index of the first state in the row by **start** (e.g. **start** = 50 for 10-th row). We can expand the previous formula to:

- For i from **start** to **start** + 5:
 - $T_{i+1,0} = T_{i,0}^5 \cdot \text{MDS}[0][0] + T_{i,1}^5 \cdot \text{MDS}[0][2] + T_{i,2}^5 \cdot \text{MDS}[0][2] + \text{RC}_{i+1,0}$
 - $T_{i+1,1} = T_{i,0}^5 \cdot \text{MDS}[1][0] + T_{i,1}^5 \cdot \text{MDS}[1][2] + T_{i,2}^5 \cdot \text{MDS}[1][2] + \text{RC}_{i+1,1}$
 - $T_{i+1,2} = T_{i,0}^5 \cdot \text{MDS}[2][2] + T_{i,1}^5 \cdot \text{MDS}[2][2] + T_{i,2}^5 \cdot \text{MDS}[2][2] + \text{RC}_{i+1,2}$

Notice that the constraints above include the state from the next row (**start** + 5).
