Chapter 1

Introduction

This document is a technical reference to the in-EVM Mina state verification project.

1.1 Overview

The project's purpose is to provide Ethereum users with reliable Mina Protocol's state proof. The project UX consists of several steps:

1. Retrieve Mina Protocol's state proof.
2. Preprocess it by generating an auxiliary proof.
3. Submit the preprocessed proof to EVM-enabled cluster.
4. Verify the proof with EVM.

Such a UX defines projects parts:

1. Mina Protocol's state retriever (O(1) Labs' or Chainsafe's protocol implementation).
2. State proof generator.
3. Ethereum RPC proof submitter.
4. EVM-based proof verifier.

The overall architecture diagram is as follows:
Each of these parts will be considered independently.

Chapter 2

State Proof Generator

This introduces a description for Mina Protocol’s state auxiliary proof generator. Crucial components which define this part design and performance are:

1. Input data format (Pickles proof data structure: [2.4.2](#))
2. Proof system used for the proof generation.
3. Circuit definition used for the proof system.

2.1 Introduction

WIP

To prove Mina blockchain’s state on the Ethereum Virtual Machine, we use Redshift SNARK[[1](#)]. RedShift is a transparent SNARK that uses PLONK[[2](#)] proof system but replaces the commitment scheme. The authors utilize FRI[[3](#)] protocol to obtain transparency for the PLONK system.

However, FRI cannot be straightforwardly used with the PLONK system. To achieve the required security level without huge overheads, the authors introduce *list polynomial commitment* scheme as a part of the protocol. For more details, we refer the reader to [[1](#)].

The original RedShift protocol utilizes the classic PLONK[[2](#)] system. To provide better performance, we generalize the original protocol for use with PLONK with custom gates [[4](#)], [[5](#)] and lookup arguments [[6](#)], [[7](#)].

2.2 Optimizations

WIP

2.2.1 Batched FRI

Instead of checking each commitment individually, it is possible to aggregate them for FRI. For polynomials f_0, \dots, f_k :

1. Get θ from transcript
2. $f = f_0 \cdot \theta^{k-1} + \dots + f_k$
3. Run FRI over f , using oracles to f_0, \dots, f_k

Thus, we can run only one FRI instance for all committed polynomials. See [[1](#)] for details.

2.2.2 Hash By Column

Instead of committing each of the polynomials, it is possible to use the same Merkle tree for several polynomials. This leads to the decrease of the number of Merkle tree paths which are required to be provided by the prover.

See [[8](#)], [[1](#)] for details.

2.2.3 Hash By Subset

Each $i + 1$ FRI round supposes the prover to send all elements from a coset $H \in D^{(i)}$. Each Merkle leaf is able to contain the whole coset instead of separate values.

See [8] for details. Similar approach is described in [1]. However, the authors of [1] use more values per leaf, that leads to better performance.

2.3 RedShift Protocol

Notations:

N_{wires}	Number of wires ('advice columns')
N_{perm}	Number of wires that are included in the permutation argument
N_{sel}	Number of selectors used in the circuit
N_{const}	Number of constant columns
\mathbf{f}_i	Witness polynomials, $0 \leq i < N_{\text{wires}}$
\mathbf{f}_{c_i}	Constant-related polynomials, $0 \leq i < N_{\text{const}}$
\mathbf{gate}_i	Gate polynomials, $0 \leq i < N_{\text{sel}}$
$\sigma(\text{col} : i, \text{row} : j) = (\text{col} : i', \text{row} : j')$	Permutation over the table

For details on polynomial commitment scheme and polynomial evaluation scheme, we refer the reader to [1].

-
1. $\mathcal{L}' = (\mathbf{q}_0, \dots, \mathbf{q}_{N_{\text{sel}}})$
 2. Let ω be a 2^k root of unity
 3. Let δ be a T root of unity, where $T \cdot 2^S + 1 = p$ with T odd and $k \leq S$
 4. Compute N_{perm} permutation polynomials $S_{\sigma_i}(X)$ such that $S_{\sigma_i}(\omega^j) = \delta^{i'} \cdot \omega^{j'}$
 5. Compute N_{perm} identity permutation polynomials: $S_{id_i}(X)$ such that $S_{id_i}(\omega^j) = \delta^i \cdot \omega^j$
 6. Let $H = \{\omega^0, \dots, \omega^n\}$ be a cyclic subgroup of \mathbb{F}^*
 7. Let $Z(X) = \prod a \in H^*(X - a)$
-

Preprocessing:

2.3.1 Prover View

1. Choose masking polynomials:

$$h_i(X) \leftarrow \mathbb{F}_{<k}[X] \text{ for } 0 \leq i < N_{\text{wires}}$$

Remark: For details on choice of k , we refer the reader to [1].

2. Define new witness polynomials:

$$f_i(X) = \mathbf{f}_i(X) + h_i(X)Z(X) \text{ for } 0 \leq i < N_{\text{wires}}$$

3. Add commitments to f_i to transcript
4. Get $\beta, \gamma \in \mathbb{F}$ from $\text{hash}(\text{transcript})$
5. For $0 \leq i < N_{\text{perm}}$

$$\begin{aligned} p_i &= f_i + \beta \cdot S_{id_i} + \gamma \\ q_i &= f_i + \beta \cdot S_{\sigma_i} + \gamma \end{aligned}$$

6. Define:

$$\begin{aligned} p'(X) &= \prod_{0 \leq i < N_{\text{perm}}} p_i(X) \in \mathbb{F}_{<N_{\text{perm}} \cdot n}[X] \\ q'(X) &= \prod_{0 \leq i < N_{\text{perm}}} q_i(X) \in \mathbb{F}_{<N_{\text{perm}} \cdot n}[X] \end{aligned}$$

7. Compute $P(X), Q(X) \in \mathbb{F}_{<n+1}[X]$, such that:

$$\begin{aligned} P(\omega) &= Q(\omega) = 1 \\ P(\omega^i) &= \prod_{1 \leq j < i} p'(\omega^j) \text{ for } i \in 2, \dots, n+1 \\ Q(\omega^i) &= \prod_{1 \leq j < i} q'(\omega^j) \text{ for } i \in 2, \dots, n+1 \end{aligned}$$

8. Compute commitments to P, Q and add them to transcript.

9. Get $\alpha_0, \dots, \alpha_5 \in \mathbb{F}$ from $\text{hash}(\text{transcript})$

10. Get τ from $\text{hash}(\text{transcript})$

11. Define polynomials (F_0, \dots, F_4 - copy-satisfiability, \mathbf{gate}_0 is PI -constraining gate)):

$$\begin{aligned} F_0(X) &= L_1(X)(P(X) - 1) \\ F_1(X) &= L_1(X)(Q(X) - 1) \\ F_2(X) &= P(X)p'(X) - P(X\omega) \\ F_3(X) &= Q(X)q'(X) - Q(X\omega) \\ F_4(X) &= L_n(X)(P(X\omega) - Q(X\omega)) \\ F_5(X) &= \sum_{0 \leq i < N_{\text{sel}}} (\tau^i \cdot \mathbf{q}_i(X) \cdot \mathbf{gate}_i(X)) + PI(X) \end{aligned}$$

12. Compute:

$$\begin{aligned} F(X) &= \sum_{i=0}^5 \alpha_i F_i(X) \\ T(X) &= \frac{F(X)}{Z(X)} \end{aligned}$$

13. $N_T := \max(N_{\text{perm}}, \mathbf{deg}_{\text{gates}} - 1)$, where $\mathbf{deg}_{\text{gates}}$ is the highest degree of the degrees of gate polynomials.

14. Split $T(X)$ into separate polynomials $T_0(X), \dots, T_{N_T-1}(X)$ ¹

15. Add commitments to $T_0(X), \dots, T_{N_T-1}(X)$ to transcript.

16. Get $y \in \mathbb{F}/H$ from $\text{hash}(\text{transcript})$

17. Run evaluation scheme with the committed polynomials and y .

Remark: Depending on the circuit, evaluation can be done also on $y\omega, y\omega^{-1}$.

18. The proof is π_{comm} and π_{eval} , where:

- $\pi_{\text{comm}} = \{f_{0,\text{comm}}, \dots, f_{N_{\text{wires}}-1,\text{comm}}, P_{\text{comm}}, Q_{\text{comm}}, T_{0,\text{comm}}, \dots, T_{N_T-1,\text{comm}}\}$
- π_{eval} is evaluation proofs for $f_0(y), \dots, f_{N_{\text{wires}}-1}(y), P(y), P(y\omega), Q(y), Q(y\omega), T_0(y), \dots, T_{N_T-1}(y)$

¹Commit scheme supposes that polynomials should be degree $\leq n$

2.3.2 Verifier View

1. Let $f_{0,\text{comm}}, \dots, f_{N_{\text{wires}}-1,\text{comm}}$ be commitments to $f_0(X), \dots, f_{N_{\text{wires}}-1}(X)$
2. $\text{transcript} = \text{setup_values} || f_{0,\text{comm}} || \dots || f_{N_{\text{wires}}-1,\text{comm}}$
3. $\beta, \gamma = \text{hash}(\text{transcript})$
4. Let $P_{\text{comm}}, Q_{\text{comm}}$ be commitments to $P(X), Q(X)$
5. $\text{transcript} = \text{transcript} || P_{\text{comm}} || Q_{\text{comm}}$
6. $\alpha_0, \dots, \alpha_5 = \text{hash}(\text{transcript})$
7. $\tau = \text{hash}(\text{transcript})$
8. $N_T := \max(N_{\text{perm}}, \deg_{\text{gates}} - 1)$, where \deg_{gates} is the highest degree of the degrees of gate polynomials.
9. Let $T_{0,\text{comm}}, \dots, T_{N_T-1,\text{comm}}$ be commitments to $T_0(X), \dots, T_{N_T-1}(X)$
10. $\text{transcript} = \text{transcript} || T_{0,\text{comm}} || \dots || T_{N_T-1,\text{comm}}$
11. $y = \text{hash}_{\mathbb{F}/H}(\text{transcript})$
12. Run evaluation scheme verification with the committed polynomials and y to check values $f_i(y), P(y), P(y\omega), Q(y), Q(y\omega), T_j(y)$.
Remark: Depending on the circuit, evaluation can be done also on $f_i(y\omega), f_i(y\omega^{-1})$ for some i .
13. Calculate:

$$\begin{aligned}
F_0(y) &= L_1(y)(P(y) - 1) \\
F_1(y) &= L_1(y)(Q(y) - 1) \\
p'(y) &= \prod p_i(y) = \prod f_i(y) + \beta \cdot S_{id_i}(y) + \gamma \\
F_2(y) &= P(y)p'(y) - P(y\omega) \\
q'(y) &= \prod q_i(y) = \prod f_i(y) + \beta \cdot S_{\sigma_i}(y) + \gamma \\
F_3(y) &= Q(y)q'(y) - Q(y\omega) \\
F_4(y) &= L_n(y)(P(y\omega) - Q(y\omega)) \\
F_5(y) &= \sum_{0 \leq i < N_{\text{sel}}} (\tau^i \cdot \mathbf{q}_i(y) \cdot \text{gate}_i(y)) + PI(y) \\
T(y) &= \sum_{0 \leq j < N_T} y^{n \cdot j} T_j(y)
\end{aligned}$$

14. Check the identity:

$$\sum_{i=0}^5 \alpha_i F_i(y) = Z(y)T(y)$$

2.4.1 Pasta Curves

Let $n_1 = 17, n_2 = 16$. Pasta curves parameters:

- $p = 2^{254} + 45560315531419706090280762371685220353$
- $q = 2^{254} + 45560315531506369815346746415080538113$
- Pallas:

$$\begin{aligned}
\mathbb{G}_1 &= \{(x, y) \in \mathbb{F}_p | y^2 = x^3 + 5\} \\
|\mathbb{G}_1| &= q
\end{aligned}$$

- Vesta:

$$\begin{aligned}
\mathbb{G}_2 &= \{(x, y) \in \mathbb{F}_q | y^2 = x^3 + 5\} \\
|\mathbb{G}_2| &= p

Notations

N_{wires}	Number of wires ('advice columns')
N_{perm}	Number of wires that are included in the permutation argument
N_{prev}	Number of previous challenges
$S_{\sigma_i}(X)$	Permutation polynomials for $0 \leq i < N_{\text{perm}}$
$pub(X)$	Public input polynomial
$w_i(X)$	Witness polynomials for $0 \leq i < N_{\text{wires}}$
$\eta_i(X)$	Previous challenges polynomials for $0 \leq i < N_{\text{prev}}$
ω	n -th root of unity

Denote multi-scalar multiplication $\sum_{s_i \in \mathbf{s}, G_i \in \mathbf{G}} [s_i]G_i$ by $\text{MSM}(\mathbf{s}, \mathbf{G})$ for $l_{\mathbf{s}} = l_{\mathbf{G}}$ where $l_{\mathbf{s}} = |\mathbf{s}|$, $l_{\mathbf{G}} = |\mathbf{G}|$. If $l_{\mathbf{s}} < l_{\mathbf{G}}$, then we use only first $l_{\mathbf{s}}$ elements of \mathbf{G}

Proof π contains (here \mathbb{F}_r is a scalar field of \mathbb{G}):

- Commitments:
 - Witness polynomials: $w_{0,\text{comm}}, \dots, w_{N_{\text{wires}},\text{comm}} \in \mathbb{G}$
 - Permutation polynomial: $z_{\text{comm}} \in \mathbb{G}$
 - Quotient polynomial: $t_{\text{comm}} = (t_{1,\text{comm}}, t_{2,\text{comm}}, \dots, t_{N_{\text{perm}},\text{comm}}) \in (\mathbb{G}^{N_{\text{perm}}} \times \mathbb{G})$
- Evaluations:
 - $w_0(\zeta), \dots, w_{N_{\text{wires}}}(\zeta) \in \mathbb{F}_r$
 - $w_0(\zeta\omega), \dots, w_{N_{\text{wires}}}(\zeta\omega) \in \mathbb{F}_r$
 - $z(\zeta), z(\zeta\omega) \in \mathbb{F}_r$
 - $S_{\sigma_0}(\zeta), \dots, S_{\sigma_{N_{\text{perm}}}}(\zeta) \in \mathbb{F}_r$
 - $S_{\sigma_0}(\zeta\omega), \dots, S_{\sigma_{N_{\text{perm}}}}(\zeta\omega) \in \mathbb{F}_r$
 - $\bar{L}(\zeta\omega) \in \mathbb{F}_r$ ²
- Opening proof o_π for inner product argument:
 - $(L_i, R_i) \in \mathbb{G} \times \mathbb{G}$ for $0 \leq i < \text{lr_rounds}$
 - $\delta, \hat{G} \in \mathbb{G}$
 - $z_1, z_2 \in \mathbb{F}_r$
- previous challenges:
 - $\{\eta_i(\xi_j)\}_j, \eta_{i,\text{comm}}$, for $0 \leq i < \text{prev}$

Remark: For simplicity, we do not use distinct proofs index i for each element in the algorithm below. For instance, we write pub_{comm} instead of $pub_{i,\text{comm}}$.

- $s^2 = x_1 + x_2 + x_3$
- $y_3 = s \cdot (x_1 - x_3) - y_1$

For point doubling $R = P + P = 2P$:

- $2s \cdot y_1 = 3x_1^2$
- $s^2 = 2x_1 + x_3$
- $y_3 = s \cdot (x_1 - x_3) - y_1$

The gate does not handle cases $\mathcal{O} + P$ or $\mathcal{O} + \mathcal{O}$. To ensure that operations with point-at-infinity are not included in the circuit's trace, copy constraint $w_6 = 0$ ($\mathbf{inf} = 0$) was introduced.

Constraints details:

- $x_2 - x_1$ zero check:
 1. $w_7 \cdot (w_2 - w_0) = 0 \iff \mathbf{same_x} \cdot (x_2 - x_1)$
If $x_1 \neq x_2$, then $\mathbf{same_x} = 0$
 2. $(w_2 - w_0) \cdot w_{10} - (1 - w_7) = 0 \iff (x_2 - x_1) \cdot \mathbf{inv}_x - (1 - \mathbf{same_x})$
If $x_1 \neq x_2$, then $\mathbf{inv}_x = (x_2 - x_1)^{-1}$
- Group law constraints:
 1. $w_7 \cdot (2w_8 \cdot w_1 - 3w_0^2) + (1 - w_7) \cdot ((w_2 - w_0 \cdot w_8 - (w_3 - w_1)) \iff \mathbf{same_x} \cdot (2s \cdot y_1 - 3x_1^2) + (1 - \mathbf{same_x}) \cdot (x_2 - x_1 \cdot s - (y_2 - y_1))$
If $x_1 = x_2$ then use doubling $2s \cdot y_1 = 3x_1^2$. Otherwise use addition $(x_2 - x_1) \cdot s = y_2 - y_1$.

2. $w_8^2 = w_0 + w_2 + w_4 \longleftrightarrow s^2 = x_1 + x_2 + x_3$
Constrains x_3 . It does not depend on x_1, x_2 equality.
3. $w_5 = w_8 \cdot (w_0 - w_4) - w_1 \longleftrightarrow y_3 = s \cdot (x_1 - x_3) - y_1$
Constrains y_3 . It does not depend on x_1, x_2 equality.
- $P + (-P)$ constraints:
 1. $(w_3 - w_1) \cdot (w_7 - w_6) = 0 \longleftrightarrow (y_2 - y_1) \cdot (\text{same_x} - \text{inf}) = 0$
We can get infinity point iff $x_1 = x_2$ and $y_1 \neq y_2$.
If $y_1 \neq y_2$ then $\text{inf} = \text{same_x}$.
 2. $(w_3 - w_1) \cdot w_9 - w_6 = 0 \longleftrightarrow (y_2 - y_1) \cdot \text{inv}_y - \text{inf}$
The prover sets $\text{inv}_y = 0$ for $y_1 = y_2$.
If $y_1 \neq y_2$ then $\text{inv}_y = (y_2 - y_1)^{-1}$

2.5.2 Variable Base Scalar Multiplication

For $R = [r]T$, where $r = 2^n + k$ and $k = [k_n \dots k_0]$, $k_i \in \{0, 1\}$:⁴

1. $P = [2]T$
2. for i from $n - 1$ to 0:
 - 2.1 $Q = k_{i+1} ? T : -T$
 - 2.2 $R = P + Q + P$
3. $R = k_0 ? R - T : R$

The first and last steps of the algorithm are verified by the unified addition and doubling circuit.

2.6 Multi-Scalar Multiplication Circuit

WIP

Input: $G_0, \dots, G_{k-1} \in \mathbb{G}, s_0, \dots, s_{k-1} \in \mathbb{F}_r$, where \mathbb{F}_r is scalar field of \mathbb{G} .

Output: $S = \sum_{i=0}^k s_i \cdot G_i$

2.6.1 Naive Algorithm

Using endomorphism:

1. $A = \infty$
2. for j from 0 to $k - 1$:
 - 2.1 $r := s_j, T := G_j$
 - 2.2 $S = [2](\phi(T) + T)$
 - 2.3 for i from $\frac{\lambda}{2} - 1$ to 0:
 - 2.3.1 $Q = r_{2i+1} ? \phi([2r_{2i} - 1]T) : [2r_{2i} - 1]T$
 - 2.3.2 $R = S + Q$
 - 2.3.3 $S = R + S$
 - 2.4 $A = A + S$

$$\text{rows} \approx k \cdot (\text{sm_rows} + 1 + 2) \approx 67k,$$

where **sm_rows** is the number of rows in the scalar multiplication circuit.

Without endomorphism:

1. $A = \infty$
2. for j from 0 to $k - 1$:
 - 2.1 $r := s_j, T := G_j$
 - 2.2 $S = [2]T$
 - 2.3 for i from $n - 1$ to 0:
 - 2.3.1 $Q = k_{i+1} ? T : -T$
 - 2.3.2 $R = S + Q$
 - 2.3.3 $S = R + S$
 - 2.4 $S = k_0 ? S - T : S$
 - 2.5 $A = A + S$

$$\text{rows} \approx k \cdot (\text{sm_rows} + 1 + 1) \approx 105k,$$

where **sm_rows** is the number of rows in the scalar multiplication circuit.

2.6.2 Simultaneous Doubling

Remark: Simultaneous doubling incurs a negligible completeness error for independently chosen random terms of the sum.

Using endomorphism:

1. $A = \sum_{j=0}^k [2](\phi(G_j) + G_j)$
2. for i from $\frac{\lambda}{2} - 1$ to 0:
 - 2.1 for j from 0 to $k - 1$:
 - 2.1.1 $r := s_j, T := G_j$
 - 2.1.2 $Q = r_{2i+1} ? \phi([2r_{2i} - 1]T) : [2r_{2i} - 1]T$
 - 2.1.3 $A = A + Q$
 - 2.2 if $i \neq 0$:
 - 2.2.1 $A = 2 \cdot A$

$$\text{rows} \approx \frac{\lambda}{2} \cdot (k \cdot \text{add_rows} + \text{dbl_rows}) + 2k \approx 64 \cdot (k + 1) \approx 66k + 64,$$

where

- **add_rows** is the number of rows in the addition circuit.
- **dbl_rows** is the number of rows in the doubling circuit.

Without endomorphism:

1. $A = \sum_{j=0}^k [2]G_j$
2. for i from $n - 1$ to 0:
 - 2.1 for j from 0 to $k - 1$:

- **add_rows** is the number of rows in the addition circuit.
- **dbl_rows** is the number of rows in the doubling circuit.

2.7 Poseidon Circuit

WIP

Mina uses Poseidon hash with width = 3. Therefore, each permutation state is represented by 3 elements and each row contains 5 states.

Denote i -th permutation state by $T_i = (T_{i,0}, T_{i,1}, T_{i,2})$.

Row	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
i	$T_{0,0}$	$T_{0,1}$	$T_{0,2}$	$T_{4,0}$	$T_{4,1}$	$T_{4,2}$	$T_{1,0}$	$T_{1,1}$	$T_{1,2}$	$T_{2,0}$	$T_{2,1}$	$T_{2,2}$	$T_{3,0}$	$T_{3,1}$	$T_{3,2}$
\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots	\vdots
$i + 10$	$T_{50,0}$	$T_{50,1}$	$T_{50,2}$	$T_{54,0}$	$T_{54,1}$	$T_{54,2}$	$T_{51,0}$	$T_{51,1}$	$T_{51,2}$	$T_{52,0}$	$T_{52,1}$	$T_{52,2}$	$T_{53,0}$	$T_{53,1}$	$T_{53,2}$
$i + 11$	$T_{55,0}$	$T_{55,1}$	$T_{55,2}$	\dots	\dots	\dots	\dots	\dots	\dots	\dots	\dots	\dots	\dots	\dots	\dots

State change constraints:

$$\text{STATE}(i + 1) = \text{STATE}(i)^\alpha \cdot \text{MDS} + \text{RC}$$

Denote the index of the first state in the row by **start** (e.g. **start** = 50 for 10-th row). We can expand the previous formula to:

- For i from **start** to **start** + 5:

- $T_{i+1,0} = T_{i,0}^5 \cdot \text{MDS}[0][0] + T_{i,1}^5 \cdot \text{MDS}[0][1] + T_{i,2}^5 \cdot \text{MDS}[0][2] + \text{RC}_{i+1,0}$
- $T_{i+1,1} = T_{i,0}^5 \cdot \text{MDS}[1][0] + T_{i,1}^5 \cdot \text{MDS}[1][1] + T_{i,2}^5 \cdot \text{MDS}[1][2] + \text{RC}_{i+1,1}$
- $T_{i+1,2} = T_{i,0}^5 \cdot \text{MDS}[2][0] + T_{i,1}^5 \cdot \text{MDS}[2][1] + T_{i,2}^5 \cdot \text{MDS}[2][2] + \text{RC}_{i+1,2}$

Notice that the constraints above include the state from the next row (**start** + 5).

Chapter 3

In-EVM State Proof Verifier

This introduces a description for in-EVM Mina Protocol state proof verification mechanism. Crucial components which define this part design are:

1. Verification architecture description.
2. Verification logic API reference.
3. Input data structures description.

3.1 Verification Logic Architecture

The verification logic is split to several parts:

1. Verification Key Definition
2. LPC/FRI auxiliary proof deserialization

3.2 Verification Logic API Reference

3.3 Input Data Structures

Chapter 4

Appendix A. In-EVM Mina State

This introduces a description for in-EVM Mina Protocol state handling mechanism which is supposed to provide a bridge user with the way to verify plaintext transactions coming from Mina database commit log on EVM.

4.1 Overview

The protocol described literally replicates Mina's commit log construction protocol on EVM. The overall process description is as follows:

Algorithm 4 Commit Log Construction Overview

1. A user retrieves a replication packet B_n containing some transaction T from Mina's commit log.
2. A user submits the replication packet B_n to the in-EVM piece of logic.
3. The in-EVM piece of logic emplaces the replication packet B_n into the backwards-linked list C .
4. The in-EVM piece of logic computes a Poseidon hash H_{B_n} of a replication packet B_n and inserts such one in a Merkle Tree T .
5. The in-EVM piece of logic uses a Merkle Tree's hash H_{B_n} of a particular replication packet B_n as an input to the state proof verification mechanism, taking the state proof from the original Mina's cluster in the same time, corresponding to the replication packet B_n sequo.
6. In case the verification of a state proof corresponding to the replication packet B_n was completed successfully, such a replication packet B_n can be considered valid and appended to the backwards-linked list, representing in-EVM Mina's commit log.
7. In case the verification of a state proof corresponding to the replication packet B_n wasn't completed successfully, then a replication packet B_n gets rejected by the in-EVM piece of logic.
8. In case there are more than a single replication packet B_n (e.g. B_{n_1} and B_{n_2}) and each of them is being considered valid, the backward-linked list used to store such replication packets turns into the tree containing several branches of backward-linked lists C_1, \dots, C_M .
9. In case several branches C_1, \dots, C_M are introduced, the Mina's Ouroboros modification chain selection rule applies to pick the

T_{n_1, n_2} allows to provide a successful transaction from $\{B_{n_1}, \dots, B_{n_2}\}$ to the Ethereum-based proof verifier later.

Ouroboros' consensus protocol chain selection rule which is supposed to handle potentially incorrect replication packet data submitted by the user (and to keep the in-EVM commit log consistent with the actual Mina's one) is defined as follows:

Here, C_{loc} is the local commit log sequence, $N = C_1, \dots, C_M$ is the list of potential commit log sequences to choose from. The function $getMinDen(C)$ outputs the minimum of all the window densities observed thus far in C .

Algorithm 5 getMinDen(C)

Let B_{last} be the last block in C .

1. if $B_{last} = G$ then // i.e., if B_{last} is the genesis block
 2. return 0
 3. else
 4. Parse B_{last} to obtain the parameter $minDen$.
 5. return $minDen$
-

The function $isShortRange(C, C)$ outputs whether or not the chains fork in the “short range” or not.

Algorithm 6 isShortRange($C1, C2$)

1. Let $prevLockcp$ and $prevLockcp$ be the $prevLockcp$ components in the 12 last blocks of $C1, C2$, respectively.
 2. if $prevLockcp = prevLockcp$ then
 3. return
 4. else
 5. return
-

Algorithm 7 maxvalid-sc($C_{loc}, N = C_1, \dots, C_M, k$)

```
// Compare  $C_{loc}$  with each candidate chain in NSet  $C_{max} \Leftrightarrow C_{loc}$  for  $i = 1, \dots, M$  do if
 $isShortRange(C_i, C_{max})$  then // Short-range fork
if  $|C_i| > |C_{max}|$  then
Set  $C_{max} \Leftrightarrow C_i$ 
end if
else //Long-range fork
if  $getMinDen(C) > getMinDen(C_{max})$  then
Set  $C_{max} \Leftrightarrow C_i$ 
end if
end if
end for
return  $C_{max}$ 
```

4.1.1 Purpose

The protocol is supposed to make it possible for the users to prove a particular transaction to the in-EVM Mina’s commit log replica to be able to prove it actually belongs to Mina’s commit log.

The overview of such a mechanism is as follows:

Algorithm 8 Transaction Plaintext Data Proving Approach

3. A user retrieves the transaction T from Mina’s database commit log
 2. A user compares the transaction T with the contents of the in-EVM Mina’s commit log representation.
 3. If a trivial comparison results in a match, Mina’s data from the transaction T can be considered valid for the in-EVM usage.
 4. Otherwise, the transaction is supposed to be rejected.
