1 Introduction

WIP

High level description according to RfP¹

- 1. Computing several hash values from the data of the proof. This involves using the Poseidon hash function with 63 full rounds both over \mathbb{F}_p and \mathbb{F}_q with round constants and MDS matrix specified for \mathbb{F}_p^2 and for \mathbb{F}_q^3 .
- 2. Checking arithmetic equations.
- 3. Performing one multi-scalar multiplication (MSM) of size $2n_2 + 4 + (2 + 25) = 63$, for which some of the bases are fixed and some are variable.
- 4. For each $i \in \{1, 2\}$, performing a multi-scalar multiplication over \mathbb{G}_i of size 2^{n_i} with a fixed array of bases, and with scalars that can be very efficiently computed from the proof.

Note that for MSM in Step 4:

$$\begin{split} \sum_{i=0}^{2^{n_k}-1} s_i \cdot G_i &= H \\ s_i &\coloneqq \prod_{\substack{0 \leq j \leq n_k \\ \text{bits}(i)[j]=1}} \phi(c_j), \end{split}$$

where:

- $\phi: \{0,1\}^{128} \to \mathbb{F}$ is defined as to_field in the implementation⁴.
- Given an integer $i < 2^{n_k}$, bits(i) is defined as the little-endian bit array of length n representing the binary expansion of i.
- $G_0, ..., G_{2^{n_k-1}} \in \mathbb{G}_k$ is a fixed sequence of group elements⁵.
- $c_0, ..., c_{n_k-1} \in \{0,1\}^{128}$ is a sequence of challenges.

We use the same 15-wires PLONK circuits that are designed for Mina.⁶

2.1 Pasta Curves

Let $n_1 = 17$, $n_2 = 16$. Pasta curves parameters:

Denote multi-scalar multiplication $\sum_{s_i \in \mathbf{s}, G_i \in \mathbf{G}} [s_i] G_i$ by $MSM(\mathbf{s}, \mathbf{G})$ for $l_{\mathbf{s}} = l_{\mathbf{G}}$ where $l_{\mathbf{s}} = |\mathbf{s}|, l_{\mathbf{G}} = |\mathbf{G}|$.

If $l_{\mathbf{s}} < l_{\mathbf{G}}$, then we use only first $l_{\mathbf{s}}$ elements of \mathbf{G}

Remark: For simplicity, we do not use distinct proofs index i for each element in the algorithm below. For instance, we write $pub_{\texttt{comm}}$ instead of $pub_{i,\texttt{comm}}$.

$$2.1.2 \ Q = k_{i+1} ? T : -T$$

$$2.1.3 \ A = A + Q$$

2.2 if $i \neq 0$:

$$2.2.1 \ A = 2 \cdot A$$

3.
$$A = A + \sum_{j=0}^{k} [1 - s_{j,0}]G_j$$

$$rows \approx \frac{2}{5}n \cdot (k \cdot add_rows + dbl_rows) + k \approx 103 \cdot (k+1) + 2k \approx 104k + 103,$$

where

- add_rows is the number of rows in the addition circuit.
- dbl_rows is the number of rows in the doubling circuit.

Poseidon Circuit 5

WIP

Mina uses Poseidon hash with width = 3. Therefore, each permutation state is represented by 3 elements and each row contains 5 states.

Denote *i*-th permutation state by $T_i = (T_{i,0}, T_{i,1}, T_{i,2})$.

State change constraints:

$$\mathtt{STATE}(i+1) = \mathtt{STATE}(i)^{\alpha} \cdot \mathtt{MDS} + \mathtt{RC}$$

Denote the index of the first state in the row by start (e.g. start = 50 for 10-th row). We can expand the previous formula to:

• For i from start to start + 5:

$$\begin{array}{l} - \ T_{i+1,0} = T_{i,0}^5 \cdot \mathtt{MDS}[0][0] + T_{i,1}^5 \cdot \mathtt{MDS}[0][2] + T_{i,2}^5 \cdot \mathtt{MDS}[0][2] + \mathtt{RC}_{i+1,0} \\ - \ T_{i+1,1} = T_{i,0}^5 \cdot \mathtt{MDS}[1][0] + T_{i,1}^5 \cdot \mathtt{MDS}[1][2] + T_{i,2}^5 \cdot \mathtt{MDS}[1][2] + \mathtt{RC}_{i+1,1} \\ - \ T_{i+1,2} = T_{i,0}^5 \cdot \mathtt{MDS}[2][2] + T_{i,1}^5 \cdot \mathtt{MDS}[2][2] + T_{i,2}^5 \cdot \mathtt{MDS}[2][2] + \mathtt{RC}_{i+1,2} \end{array}$$

$$T_{i+1,1} = T_{i,0}$$
 and $T_{i,1} = T_{i,1}$ and $T_{i,1} = T_{i,2}$ and $T_{i,2} = T_{i,2}$ and $T_{i,1} = T_{i,2}$ and $T_{i,2} = T_{i,2}$ and $T_{i,2} = T_{i,3}$ and $T_{i,2} = T_{i,3}$ and $T_{i,3} = T_{i,3}$ and $T_$

Notice that the constraints above include the state from the next row (start + 5).

- $(w_2 + w_3 \cdot w_5) \cdot w_6 = w_8$
