1   Introduction

WIP

High level description according to RfP[1]

1. Computing several hash values from the data of the proof. This involves using the Poseidon hash function with 55 full rounds both over $\mathbb{F}_p$ and $\mathbb{F}_q$ with round constants and MDS matrix specified for $\mathbb{F}_p$[2] and for $\mathbb{F}_q$[3].

2. Checking arithmetic equations.

3. Performing one multi-scalar multiplication (MSM) of size $2n_2 + 4 + (2 + 25) = 63$, for which some of the bases are fixed and some are variable.

4. For each $i \in \{1, 2\}$, performing a multi-scalar multiplication over $\mathbb{G}_i$ of size 2^{n_i} with a fixed array of bases, and with scalars that can be very efficiently computed from the proof.

Note that for MSM in Step 4:

$$\sum_{i=0}^{2^{n_k}-1} s_i \cdot G_i = H$$
$$s_i := \prod_{\substack{0 \le j \le n_k \\ \text{bits}(i)[j]=1}} \phi(c_j),$$

where:

- $\phi\colon \{0,1\}^{128} \to \mathbb{F}$ is defined as `to_field` in the implementation[4].
- Given an integer $i < 2^{n_k}$, bits(i) is defined as the little-endian bit array of length n representing the binary expansion of i.
- $G_0, ..., G_{2^{n_k}-1} \in \mathbb{G}_k$ is a fixed sequence of group elements[5].
- $c_0, ..., c_{n_k-1} \in \{0,1\}^{128}$ is a sequence of challenges.

We use the same 15-wires PLONK circuits that are designed for Mina.[6]

2.1 Pasta Curves

Let $n_1 = 17$, $n_2 = 16$. Pasta curves parameters:

- $p = 2^{254} + 45560315531419706090280762371685220353$
- $q = 2^{254} + 45560315531506369815346746415080538113$

$$|\mathbb{G}_2| = p$$

2.2 Verification Algorithm

Proof π constains (here $\mathbb{F}_r$ is a scalar field of $\mathbb{G}$):

    - Witness polynomials: $w_{0,\texttt{comm}}, ..., w_{N_{\texttt{wires}},\texttt{comm}} \in \mathbb{G}$
    - Permutation polynomial: $z_{\texttt{comm}} \in \mathbb{G}$
    - Quotient polynomial: $t_{\texttt{comm}} = (t_{1,\texttt{comm}}, t_{2,\texttt{comm}}, ..., t_{N_{\texttt{perm}},\texttt{comm}}) \in (\mathbb{G}^{N_{\texttt{perm}}} \times \mathbb{G})$
- Evaluations:
    - $w_0(\zeta), ..., w_{N_{\texttt{wires}}}(\zeta) \in \mathbb{F}_r$
    - $w_0(\zeta\omega), ..., w_{N_{\texttt{wires}}}(\zeta\omega) \in \mathbb{F}_r$
    - $z(\zeta), z(\zeta\omega) \in \mathbb{F}_r$
    - $S_{\sigma_0}(\zeta), ..., S_{\sigma_{N_{\texttt{perm}}}}(\zeta) \in \mathbb{F}_r$
    - $S_{\sigma_0}(\zeta\omega), ..., S_{\sigma_{N_{\texttt{perm}}}}(\zeta\omega) \in \mathbb{F}_r$

    - $\delta, \hat{G} \in \mathbb{G}$
    - $z_1, z_2 \in \mathbb{F}_r$
- previous challenges:
    - $\{\eta_i(\xi_j)\}_j, \eta_{i,\texttt{comm}}$, for $0 \leq i < \texttt{prev}$

Denote multi-scalar multiplication $\sum\limits_{s_i \in \mathbf{s}, G_i \in \mathbf{G}} [s_i]G_i$ by $\texttt{MSM}(\mathbf{s}, \mathbf{G})$ for $l_\mathbf{s} = l_\mathbf{G}$ where $l_\mathbf{s} = |\mathbf{s}|$, $l_\mathbf{G} = |\mathbf{G}|$.
If $l_\mathbf{s} < l_\mathbf{G}$, then we use only first $l_\mathbf{s}$ elements of $\mathbf{G}$

Remark: For simplicity, we do not use distinct proofs index i for each element in the algorithm below. For instance, we write $pub_{\texttt{comm}}$ instead of $pub_{i,\texttt{comm}}$.

State change constraints:

$$\texttt{STATE}(i + 1) = \texttt{STATE}(i)^{\alpha} \cdot \texttt{MDS} + \texttt{RC}$$

Denote the index of the first state in the row by `start` (e.g. `start` $= 50$ for 10-th row). We can expand the previous formula to:

- For i from `start` to `start` $+ 5$:
    - $T_{i+1,0} = T_{i,0}^5 \cdot \text{MDS}[0][0] + T_{i,1}^5 \cdot \text{MDS}[0][2] + T_{i,2}^5 \cdot \text{MDS}[0][2] + \text{RC}_{i+1,0}$
    - $T_{i+1,1} = T_{i,0}^5 \cdot \text{MDS}[1][0] + T_{i,1}^5 \cdot \text{MDS}[1][2] + T_{i,2}^5 \cdot \text{MDS}[1][2] + \text{RC}_{i+1,1}$
    - $T_{i+1,2} = T_{i,0}^5 \cdot \text{MDS}[2][2] + T_{i,1}^5 \cdot \text{MDS}[2][2] + T_{i,2}^5 \cdot \text{MDS}[2][2] + \text{RC}_{i+1,2}$

Notice that the constraints above include the state from the next row (`start` $+ 5$).
